

Shape Analysis Using Separation Logic

Author

Tomáš Brablec

Supervisors

Tomáš Dacík, Tomáš Vojnar

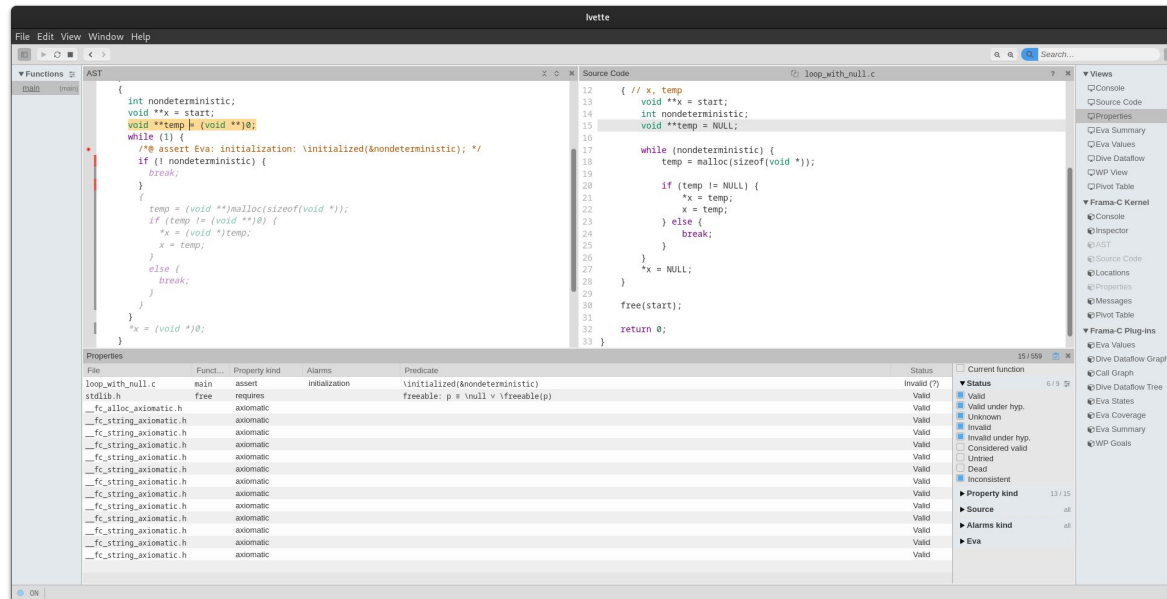

- Manual memory management creates a whole class of bugs
- Memory errors are a common source of security vulnerabilities
- Dynamic analysis does not prove correctness
- There is space for static analysis and possibly formal verification

Microsoft: Around 70% of CVEs are memory related

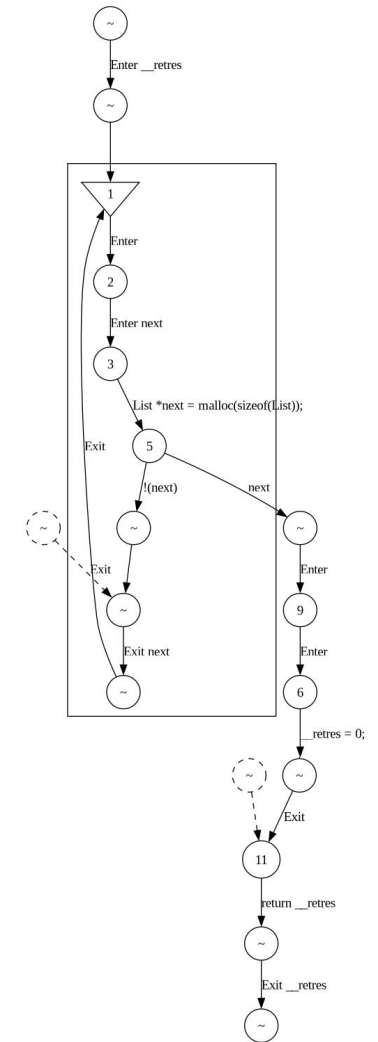

- The goal is to develop a prototype of a **static shape analyser**
- Use **separation logic** to represent program states
- Focus on programs that work with **linked lists**
- Utilize the Frama-C framework to simplify implementation
- Use the Astral solver to efficiently work with separation logic

- Modular framework for analysis of C code
- The program is represented in the C Intermediate Language (CIL)
- CIL is based on a modified AST with extra information
- a GUI frontend called Ivette is under development

Software Analyzers

- Runs on the **Control Flow Graph** (CFG) of the input code
- Each node of the CFG is assigned an analysis state
- States of all nodes are updated until a fixpoint is found for all of them
- The plugin defines a transfer function that computes new states for nodes based on the states of predecessor nodes
- Updates are propagated along the edges of the CFG

example of a CFG

- Developed to solve the problem of globality in analyses
- SL formulae describe the state of the heap
- Enables **abstraction over linked lists** of arbitrary length
- Dedicated solver for SL – **Astral**

$\varphi ::= x = y \mid x \neq y$	(pure atoms)
$\mid x \mapsto y \mid \text{ls}(x, y)$	(spatial atoms)
$\varphi ::= \varphi \wedge \varphi \mid \varphi \vee \varphi \mid \varphi \wedge_{\neg} \varphi \mid \neg \varphi$	(boolean connectives)
$\varphi ::= \varphi * \varphi \mid \varphi -\circ \varphi$	(spatial connectives)

syntax of SL formulae

Astral

- Derives the shapes of data structures on the heap
- Previous work defines abstraction rules for a minimal language
- My objectives:
 - adapt this method to work on a subset of C
 - use Astral for solving SL formulae
- The use of Astral provides greater flexibility than the original method

- Currently limited to programs without function calls
- **Preprocessing** is done on the AST to simplify statements
- Constants are removed, field accesses are converted to dereferences
- During the analysis, the formulae are **simplified** between statements
- Results are reported using **Ivette**

Original	Preprocessed
<code>int main() {</code>	<code>int main() {</code>
	<code>void *_nil = 0;</code>
<code>List *list = (List *)malloc(sizeof(List));</code>	<code>List *list = malloc(sizeof(List));</code>
<code>if (list == NULL) return 1;</code>	<code>if (list == _nil) return 1;</code>
<code>list->next = NULL;</code>	<code>*list = _nil;</code>
<code>list->data = 42;</code>	

preprocessing example

- The visit of every relevant statement **modifies the state formulae**
- `malloc` splits the state into the cases of successful and failed allocation
- Dereference of a list node splits the state according to the length of the list

Analyzed statement	State formulae
	$\varphi := \text{emp}$
<code>a = malloc(8);</code>	
	$\varphi_1 := (a \mapsto l_0)$ $\varphi_2 := (a = \text{nil})$
	$\varphi := \text{ls}(x, \text{nil})$
<code>y = x->next;</code>	
	$\varphi_1 := (x \mapsto y) * \text{ls}(y, \text{nil})$ $\varphi_2 := (x \mapsto y) * (y = \text{nil})$

- The abstraction ensures that the analysis will terminate
- Between statements, the formulae are also simplified and deduplicated
- This is done to speed up the analysis

Type of simplification	Input formula	Output formula
abstraction to list segments	$(x \mapsto l_0) * (l_0 \mapsto y)$	$ls(x, y)$
removal of variables at the end of their scope	$(x = y) * (y \mapsto z)$	$(y \mapsto z)$
removal of irrelevant inequalities	$(x \mapsto y) * (y \neq l_0)$	$(x \mapsto y)$
removal of unsatisfiable formulae	$(x \mapsto y) * (x = y)$	

examples of simplifications

- The analyzed code constructs a linked list, traverses all nodes, and then deallocates it
- The following program works with a **singly linked list**

```
typedef struct List {  
    struct List *next;  
    int data;  
} List;
```

- The program starts by allocating the first node

```
int main() {  
    List *start = malloc(sizeof(List));  
    if (start == NULL)  
        return 1;  
}
```

- At this point, the state is represented by a formula

$$(_nil = nil) * (start \mapsto alloc_0) * (start \neq _nil)$$

- Then the **whole list is allocated**, up to a nondeterministic length

```
{ // construct a linked list of unknown size
  List *list = start;
  list->next = NULL;
  int nondeterministic;
  while (nondeterministic) {
    List *next = malloc(sizeof(List));
    if (next == NULL)
      return 1;
    list->next = next;
    list = list->next;
  }
  list->next = NULL;
}
```

- After this, the state is

$$_nil = nil * ls(start, _nil) * start \neq _nil$$

- After traversing the list, the **state stays the same** since the shape of the data structure did not change

```
{ // walk to the end of the list
  List *list = start;
  while (list != NULL) {
    List *next = NULL;
    next = list->next;
    list->data = 42;
    list = next;
  }
}
```

- At last, all nodes are deallocated

```
{ // free the list
    List *list = start;
    while (list != NULL) {
        List *next = NULL;
        next = list->next;
        free(list);
        list = next;
    }
}
```

- The state is changed to reflect that

$$(_nil = nil) * (start \neq _nil)$$

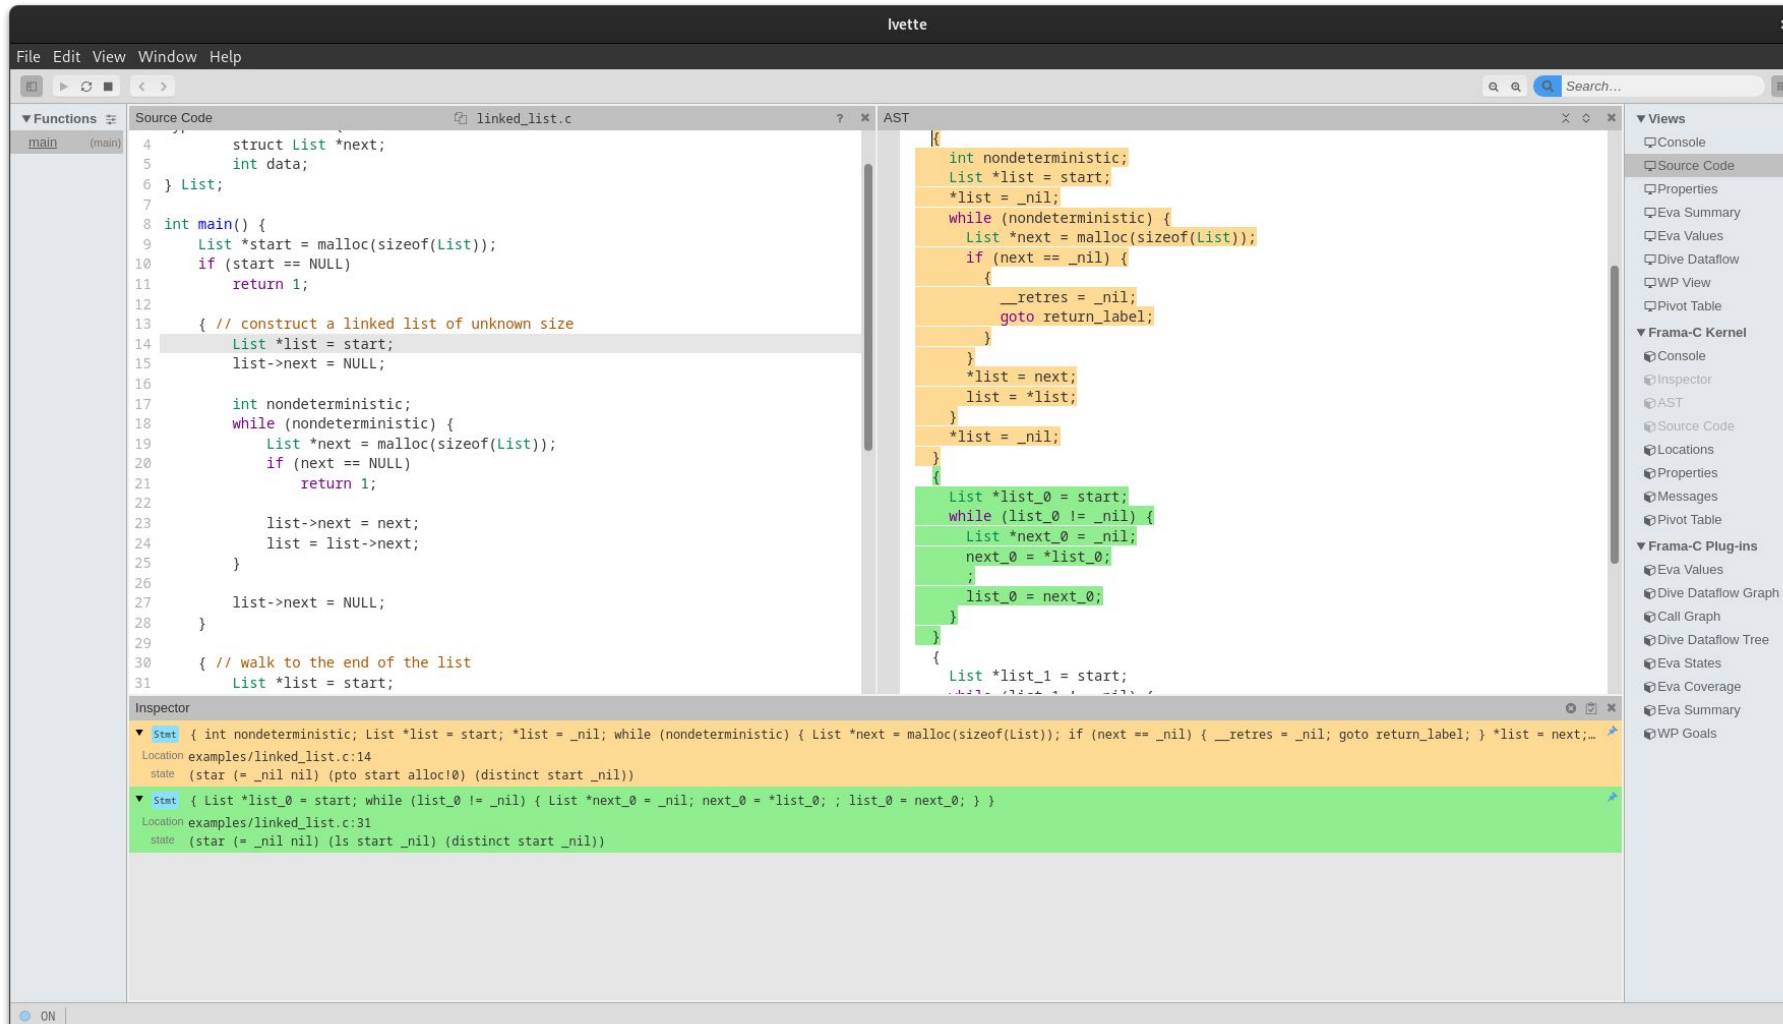

- The analysis is not only able to detect the shape of data in a correct program, it can also **detect memory errors**
- If we try to access the list after deallocation, the bug is detected

```
start->next = NULL; // use after free
```

- After adding this line below the deallocation, an error is raised

```
[SLplugin] examples/linked_list.c:54: Failure:  
    detected a dereference of an unallocated variable
```

- These results can be viewed using the Ivette GUI extension

The screenshot displays the Ivette GUI extension interface. The main window is titled 'Ivette' and contains three panes: Source Code, AST, and Inspector.

Source Code Pane: Shows the source code of a file named 'linked_list.c'. The code defines a linked list structure and a main function. The main function initializes a list, constructs a linked list of unknown size, and walks to the end of the list.

```

4 struct List *next;
5 int data;
6 } List;
7
8 int main() {
9     List *start = malloc(sizeof(List));
10    if (start == NULL)
11        return 1;
12
13    // construct a linked list of unknown size
14    List *list = start;
15    list->next = NULL;
16
17    int nondeterministic;
18    while (nondeterministic) {
19        List *next = malloc(sizeof(List));
20        if (next == NULL)
21            return 1;
22
23        list->next = next;
24        list = list->next;
25    }
26
27    list->next = NULL;
28 }
29
30 // walk to the end of the list
31 List *list = start;

```

AST Pane: Shows the Abstract Syntax Tree (AST) for the source code. The AST is a tree structure representing the code's semantics. The root node is a function call 'main', which has a body containing a loop and a final assignment.

```

{
  int nondeterministic;
  List *list = start;
  *list = _nil;
  while (nondeterministic) {
    List *next = malloc(sizeof(List));
    if (next == _nil) {
      _retres = _nil;
      goto return_label;
    }
    *list = next;
    list = *list;
  }
  *list = _nil;
  List *list_0 = start;
  while (list_0 != _nil) {
    List *next_0 = _nil;
    next_0 = *list_0;
    list_0 = next_0;
  }
  List *list_1 = start;
}

```

Inspector Pane: Shows the state of the program at the current execution point. The state is a map of variables and their values. The current state is shown for the location 'examples/linked_list.c:31'.

```

State {
  star = (_nil nil) (ls start _nil) (distinct start _nil)
}

```

The right sidebar contains a 'Views' panel with various views and tools, including Console, Source Code, Properties, Eva Summary, Eva Values, Dive Dataflow, WP View, Pivot Table, Frama-C Kernel, and Frama-C Plug-ins.

- Support the **analysis of function calls**, possibly with caching of results
- Preprocess complex statements to enable the analysis of more programs
- Support global and static variables
- Most importantly, **extend the analysis to more complex data structures**
(doubly linked lists, nested lists)
- Benchmark the analysis and compare it to other solutions

- Studied topics: Frama-C framework, dataflow analysis, separation logic, Astral solver, shape analysis
- Implemented a prototype of shape analysis using separation logic, able to analyze simple programs that work with linked lists
